Dissertation Abstracts**Recreation Elasticities of Mountain Snowpack and Implications for a Changing Climate**

with Peter Christensen

Dissertation Chapter I

Throughout the winter months in mountain towns across the globe, humans anxiously monitor ever-changing snowpack conditions to decide when and where to ski. We model the behavioral response to this climate amenity by pairing a unique panel of 13 million short-term property rental transactions with daily local weather, daily resort snowpack, and daily resort snowfall in every major ski market across the United States. Matching the spatial and temporal variation in the level of the amenity with that of related market transactions, we derive state-specific snowpack elasticities and model recreation patterns throughout a typical season. Lastly, we combine downscaled projections of resort-specific snowpack under future climate scenarios to estimate within and across season visitation patterns during mid and late-century conditions. Our model predicts that resort markets could face reductions in local snow-related revenue of -40% to -80%, almost twice as large as previous estimates suggest. This translates to a lower-bound on the annual willingness to pay to avoid reductions in snowpack between \$1.64 billion (RCP4.5) and \$2.36 billion (RCP8.5) by the end of the century.

A Recreational Demand Model for Snowpack*Dissertation Chapter II*

I estimate demand parameters for wintertime recreation in the contiguous United States. I make two primary contributions in this paper: 1) I provide estimates of the MWTP for mountain snowpack at the national and regional levels; and 2) I construct a matrix of substitution elasticities between US resort markets. Both contributions invoke random utility to estimate structural parameters in the utility functions of alpine skiers. For the first contribution (1), I maintain trip-level micro data to estimate marginal utilities subsequent MWTP. I develop a new instrument to address price endogeneity concerns for use in a 2SLS instrumental variables approach. For the second contribution (2), I aggregate the trip-level data to market-level and calculate daily market shares. This allows me to recover substitution patterns in the form of elasticities, providing insight into how skiers move across markets based on changes in mountain snowpack. Both contributions are important for understanding consumer welfare in the alpine skiing market and the implications of a changing climate.

Overlooked Benefits of Nutrient Reductions in the Mississippi River Basin

with Amy W. Ando

Dissertation Chapter III

Improvements in local surface water quality in the Mississippi River Basin (MRB) can contribute to the regional environmental goals of reducing hypoxia in the Gulf of Mexico. To inform estimates of the benefits of water quality policy, we use a choice experiment survey in a typical sub-watershed of the MRB to estimate willingness to pay for local environmental improvements and helping to reduce hypoxia far downstream. We find that residents place large values on reduced local algal blooms, improved local fish populations and diversity, and meeting local commitments to help with the regional environmental problem.
